LEARNING DIARY, MOBILE MODULE

LEARNING DIARY

Introduction

Firstly, in introduction it's a good reminder how android studio works and what different tools need to be installed. Basic tools and emulator were also a good reminder to check sometimes how application looks on devices. Through different files and where everything can be found is good that tutorial cover all basics. How to add variables to java is a good skill to handle at the beginning. How to use debugging in android studio was new skill me to learn.

Core Elements

How to create new activity is important when creating android application. As simple as it looks it is good reminder that android has gallery of different activities. Basic commands are good to know how to move between different activities. How to put extra when launching intent is fun addition when launching different activities and might show its usefulness in the future applications. It's useful to know how to go outside the application if necessary.

Lists, Layouts and Images

Building listview and its objects were very educational. Hard to remember part were creating adapter and how many steps each part should add in the application and when need adapter etc. It's still amaze me how easily some parts are done like adding image. Scaling image to match hardware is new and useful thing to learn. Multiple views and different elements and how to handle connections between them are interesting and good knowledge when developing mobile applications.

Course Project

For the course project I build Todo-application. In the application you get a list of Todo's which you can check when done. Application also contains add button which takes software in another activity where a new Todo can be written and added, when adding a new activity it takes user back to Todo-list. Todo-list activity also contains button which user can delete all done Todo's with one click of the button. To keep building course simple, there haven't been added any database where Todo's are saved. Application has one hard coded Todo

when opening application and it keeps Todo's safe while application is open, but it erases memory while shutting down application.

I have tried to use multiple different objects to learn how to build complete application and how to use them to make applications look good. Some are same objects, but I tried sine different building blocks to keep project mine and not straight follow up. Building applications basic functions I have followed mainly tutorial videos. Building own application has been educational experience.
